# EPIC L2 volcanic SO<sub>2</sub> algorithm (MS\_SO2) and product

- State vector [*Fisher et al., AMT, 2019*]

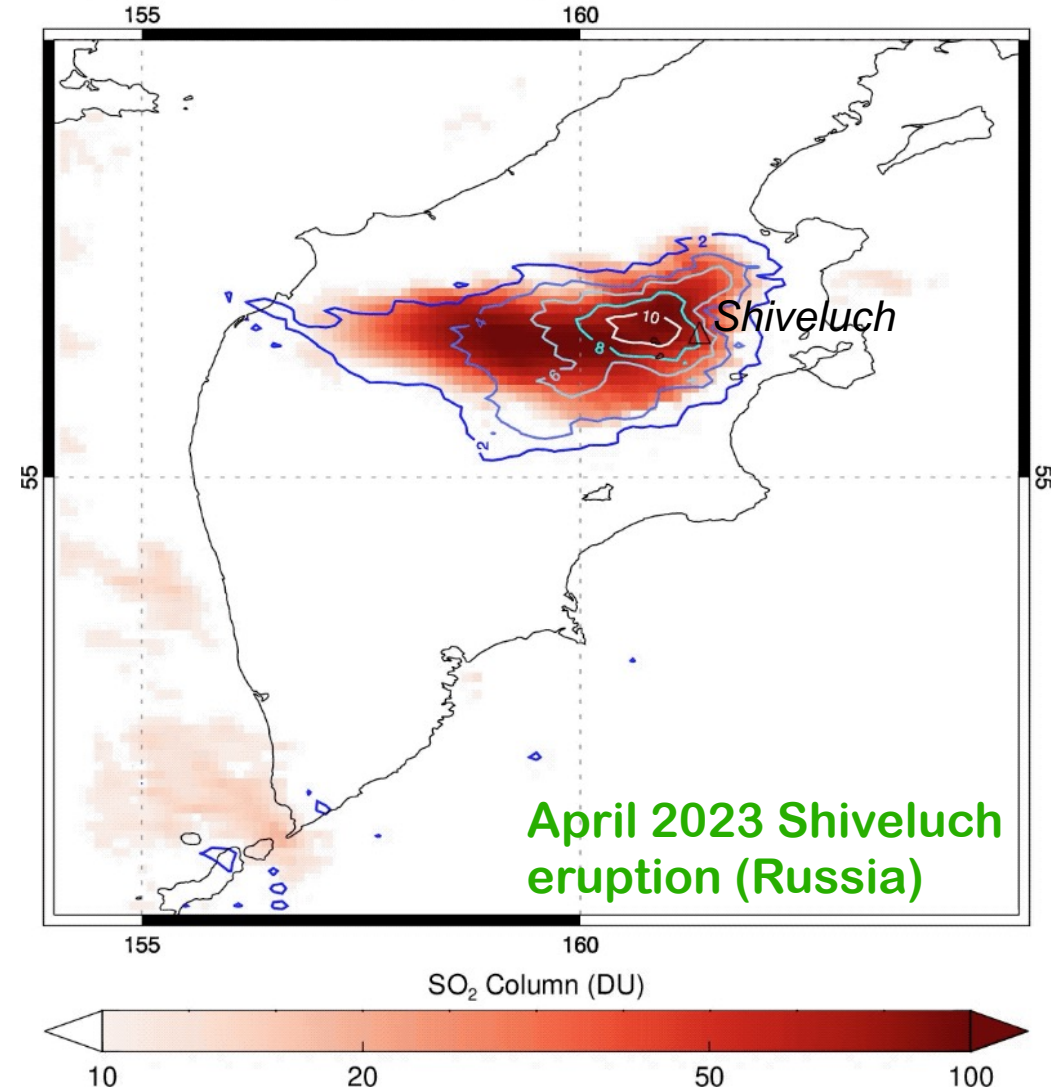

$$\mathbf{x} = \begin{pmatrix} \text{SO}_2 \\ \text{O}_3 \\ \text{dR/d}\lambda \\ R \end{pmatrix} \longrightarrow \text{UV Aerosol Index (UVAI)}$$

- Uses 4 EPIC UV channels
- Step 1 -> initial estimates
- Step 2 -> reduce artifacts
  - Earth rotation
  - Geolocation errors
  - Cloud noise
  - Ozone variability
- We process the EPIC volcanic SO<sub>2</sub> product 'on demand' after significant eruptions (4,092 granules on ASDC)
- Radiance LUTs generated for SO<sub>2</sub> center of mass altitudes (CMAs) of 3, 5, 8 and 18 km for research use (L2 product = 13 km)

[*Carn et al., GRL, 2018; Gorkyavi et al., Frontiers Rem. Sens., 2021; Carn et al., Frontiers Earth Sci., 2022*]

DSCOV/EPIC - 04/10/2023 22:31 UT

SO<sub>2</sub> mass: 78.48 kt; SO<sub>2</sub> max: 103.61 DU at lon: 159.18, lat: 56.60

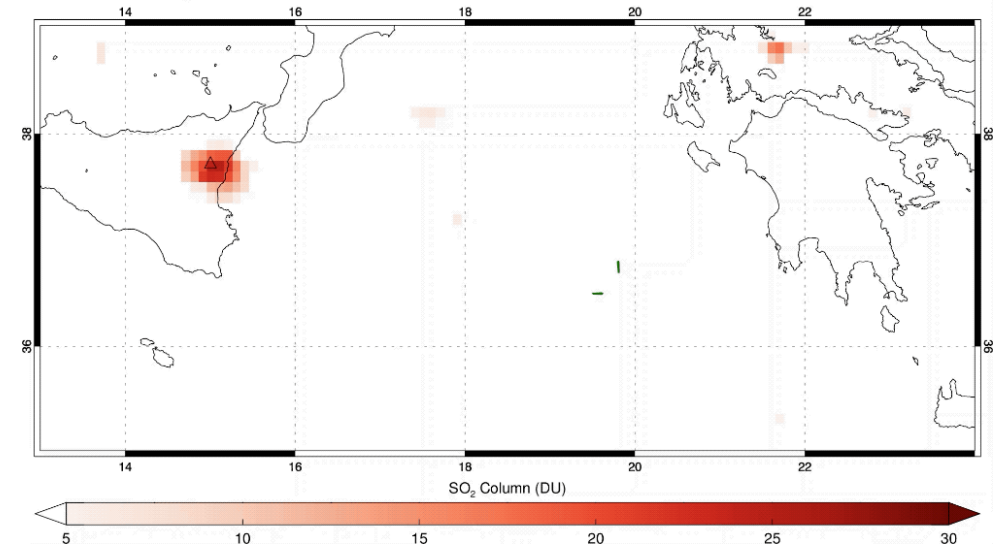

# Recent volcanic eruptions detected by EPIC (2021 - )

DSCOVER/EPIC - 05/21/2023 07:37 UT

SO<sub>2</sub> mass: 1.86 kt; SO<sub>2</sub> max: 25.71 DU at lon: 15.10, lat: 37.75

- Significant EPIC L2 SO<sub>2</sub> data processing effort in 2023 – identified many eruptions of Etna volcano (Italy).
- Largest eruption of 2023 (to date) is Shiveluch (Russia) in April.
- Prepared protocols for higher-cadence (~20 minute) EPIC imaging of a future volcanic eruption (requires 1-2 days advance warning).

# Pre-eruptive gas accumulation in magma reservoirs

- Pre-eruptive accumulation of volcanic gases in magma reservoirs may trigger some eruptions.
- Usually not possible to detect accumulated gases before eruptions.
- Accumulated gas 'gradients' could be manifested in volcanic emissions during eruptions (high-cadence imaging of fresh eruption plumes required).
- Volcanic ash measurements also needed, to quantify erupted mass and assess impact of ash on  $\text{SO}_2$  data.

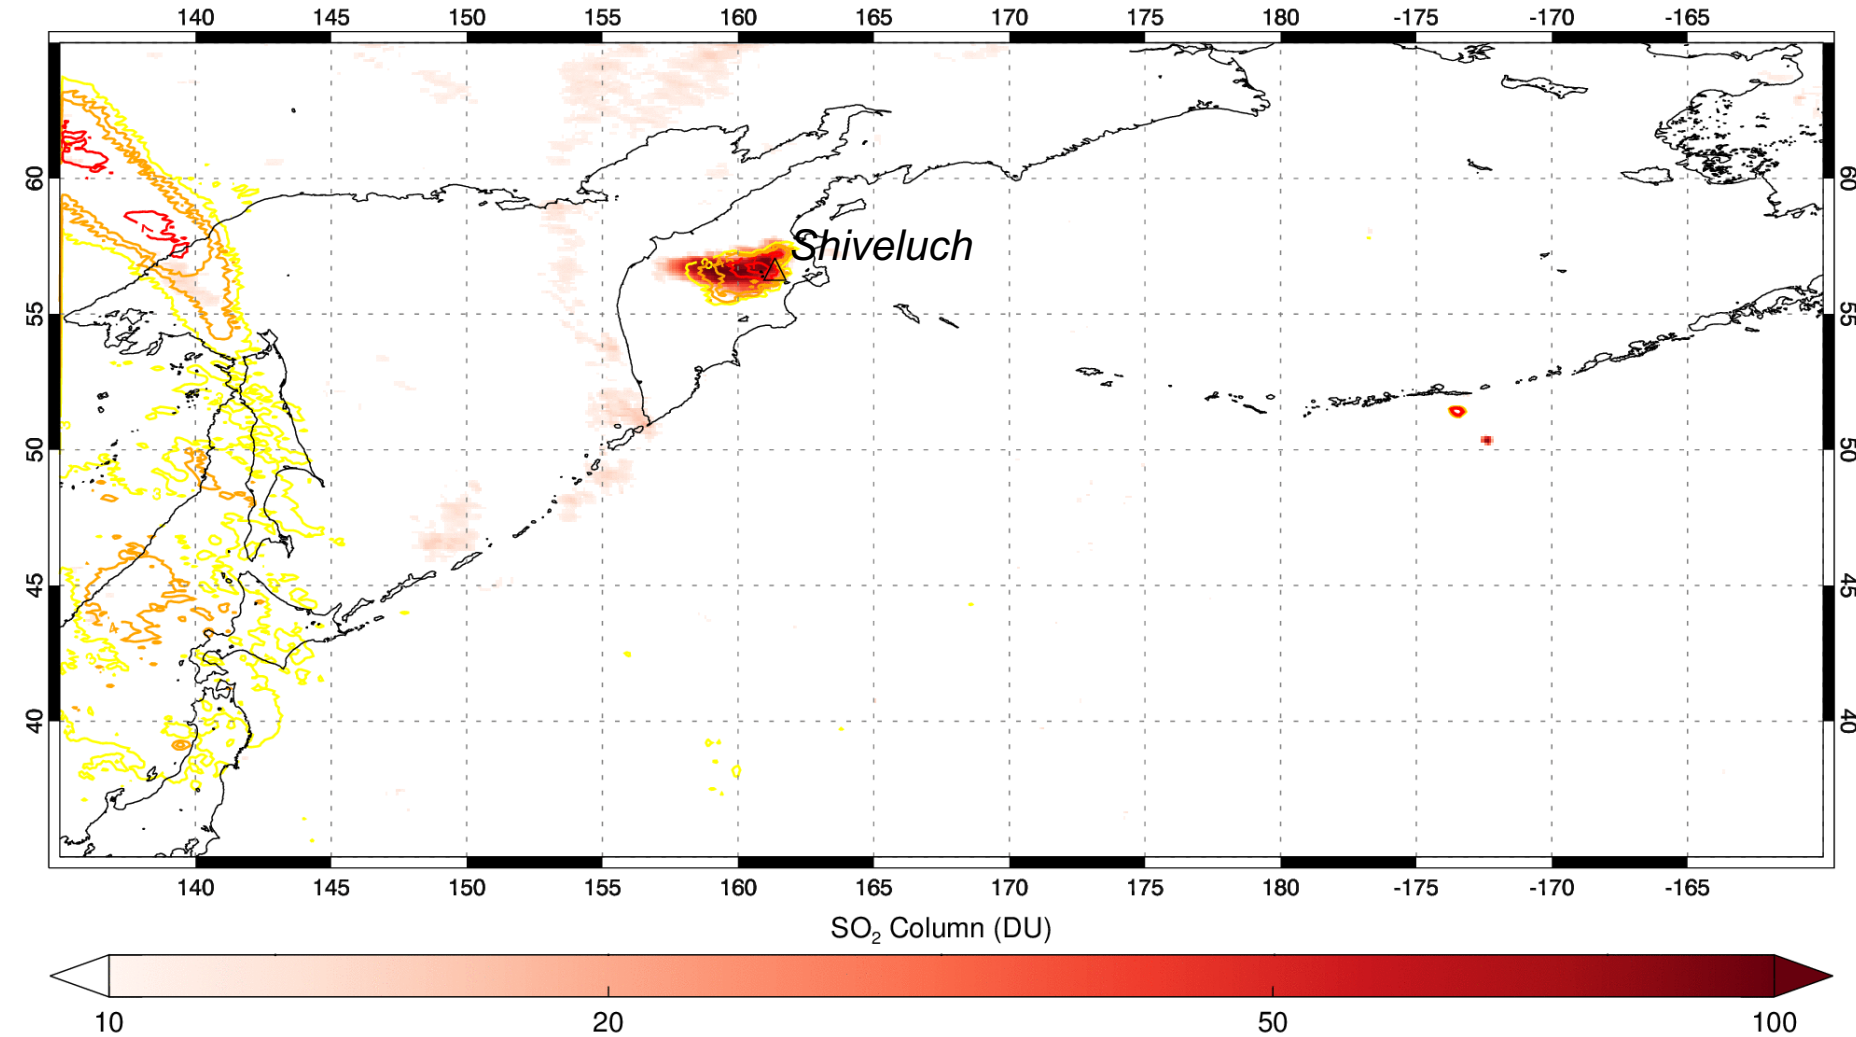

# Shiveluch eruption (April 2023) – volcanic SO<sub>2</sub>, ash and dust

# Shiveluch eruption (April 2023) – volcanic SO<sub>2</sub>, ash and dust

DSCOVN/EPIC - 04/10/2023 22:31 UT

SO<sub>2</sub> mass: 147.42 kt; SO<sub>2</sub> max: 103.61 DU at lon: 159.18, lat: 56.60

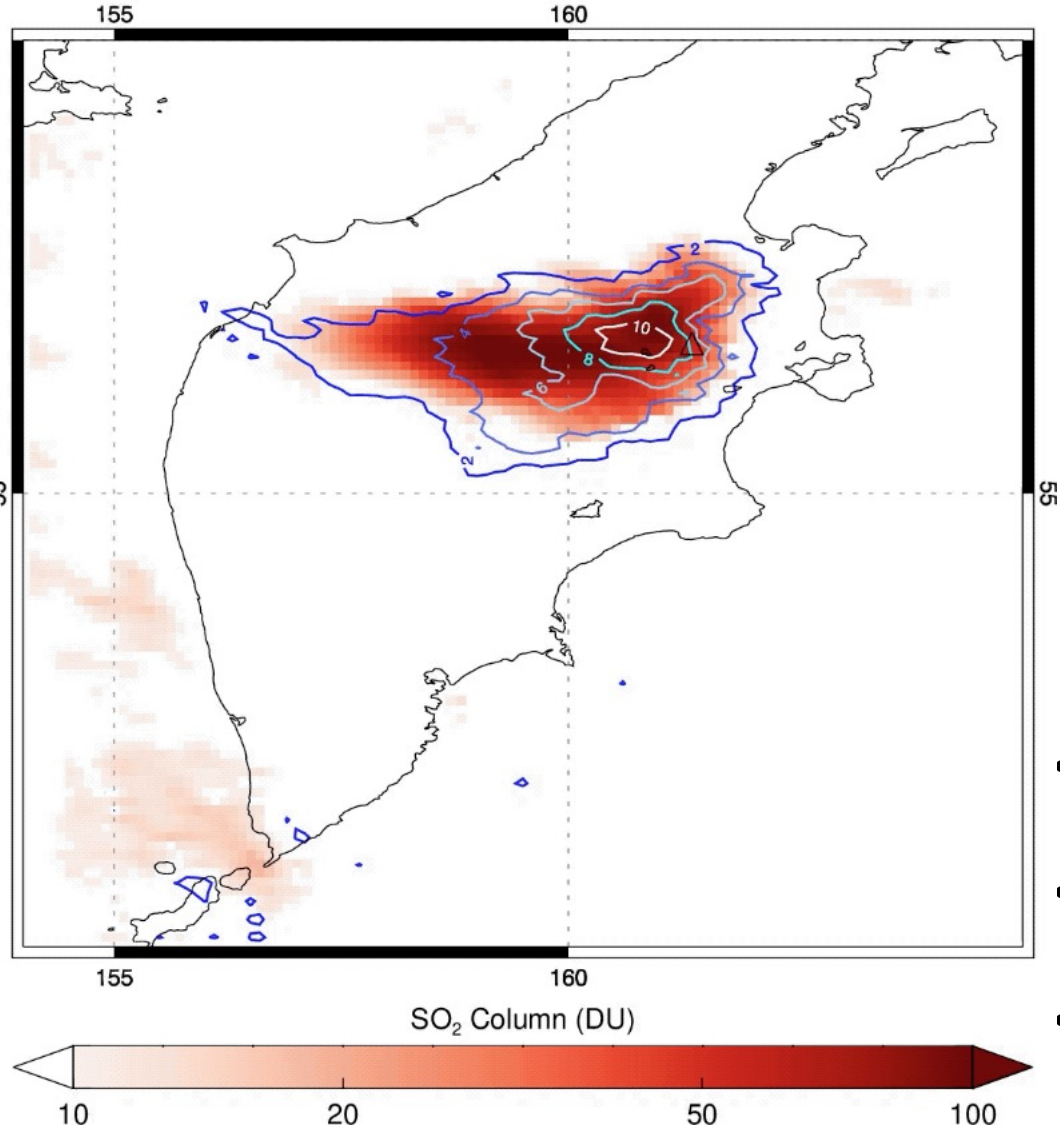

- EPIC SO<sub>2</sub> and UV Aerosol Index (UVAI)
- April 10-12, 2023
- Simultaneous observations of volcanic SO<sub>2</sub>, ash and Asian dust transport.
- ‘Volcanic ash’ later reported (Apr 14) over Pacific NW, causing flight cancelations, but may have been dust?

# 2023 Sheveluch eruption (Kamchatka, Russia)

DSCOVN/EPIC - 04/10/2023 22:31 UT

SO<sub>2</sub> mass: 78.48 kt; SO<sub>2</sub> max: 103.61 DU at lon: 159.18, lat: 56.60

- EPIC UVAI decreases quickly after eruption
- Consistent with heavy fallout of volcanic ash in Kamchatka
- Volcanic ash interference on SO<sub>2</sub> measurements possible

# Shishaldin eruption (Sept 2023) – volcanic SO<sub>2</sub>, ash & smoke

SNPP/VIIRS/OMPS Aerosol Index – Sept 25, 2023

# Shishaldin eruption (Sept 2023) – volcanic SO<sub>2</sub>, ash & smoke

DSCOVN/EPIC - 09/25/2023 18:55 UT

SO<sub>2</sub> mass: 43.30 kt; SO<sub>2</sub> max: 39.53 DU at lon: -157.51, lat: 54.25

- EPIC SO<sub>2</sub> and UV Aerosol Index (UVAI)
- Sept 25, 2023
- UVAI detects smoke and volcanic ash – ash signal tracks with SO<sub>2</sub> in EPIC data

# 2022 Mauna Loa eruption (Hawaii)

DSCOVR/EPIC - 12/01/2022 18:08 UT

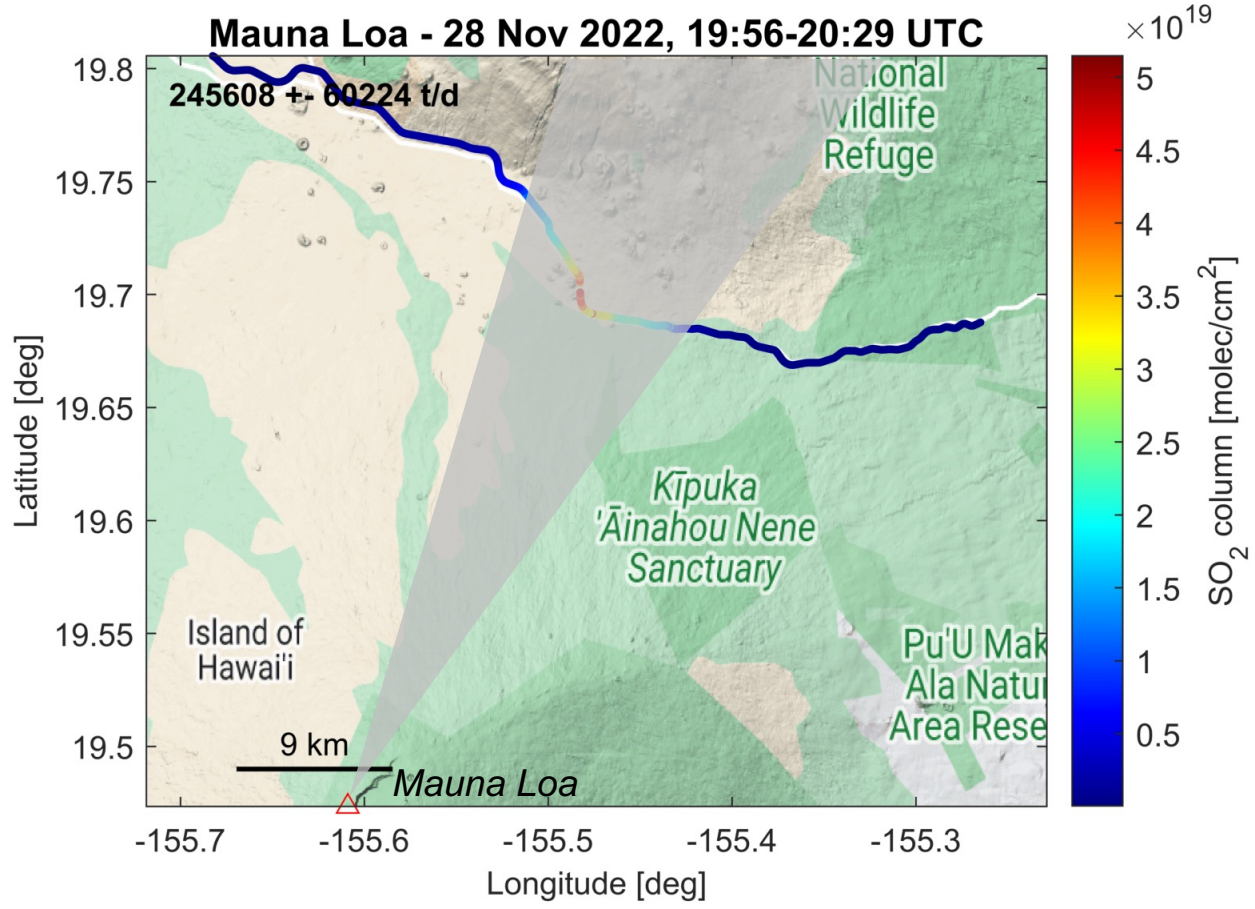

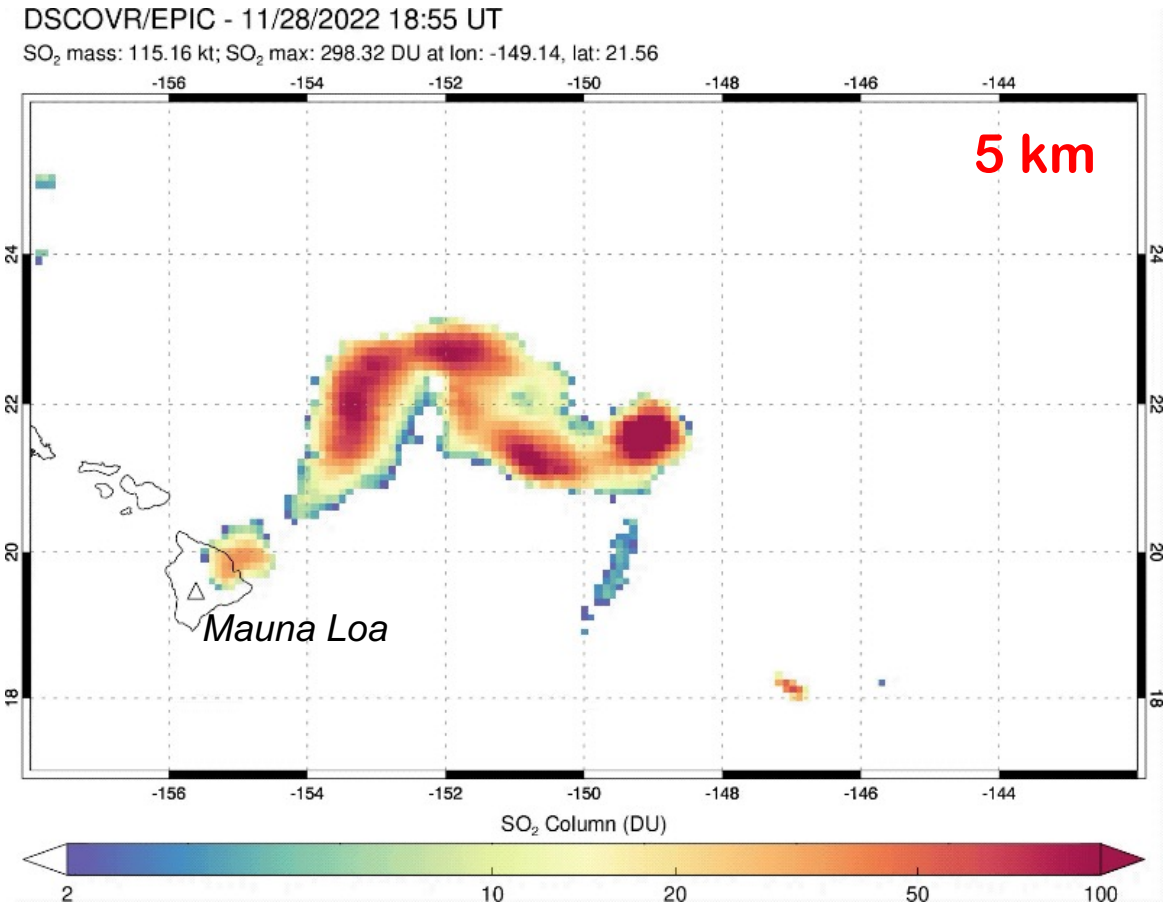

SO<sub>2</sub> mass: 48.21 kt; SO<sub>2</sub> max: 22.40 DU at lon: -141.61, lat: 11.16

Data: NASA/DSCOVR Science Team  
Processed by: S. Carn (scarn@mtu.edu)

- EPIC detects exponential decrease in SO<sub>2</sub> emissions, as expected during effusive eruptions.
- High-cadence permits isolation of 'fresh' SO<sub>2</sub> emissions, improving SO<sub>2</sub> flux calculations.

# 2022 Mauna Loa eruption (Hawaii)

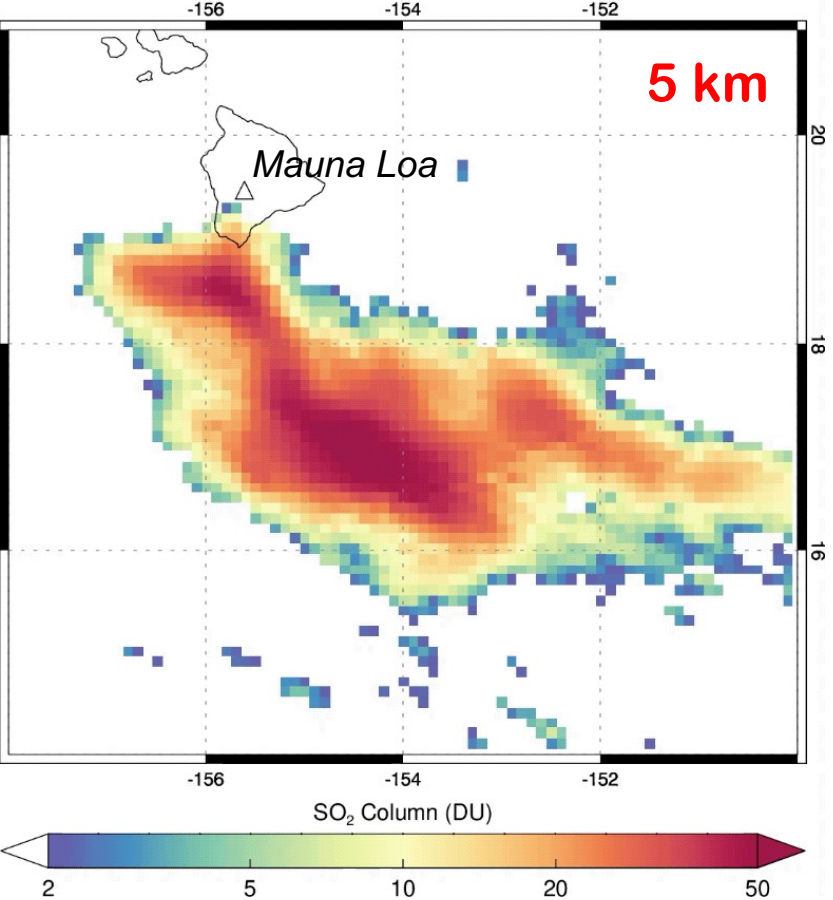

Ground-based DOAS SO<sub>2</sub> data (C. Kern/USGS CVO)

- U.S. Geological Survey (USGS) Volcanic Emissions Group measured SO<sub>2</sub> emissions during eruption
- EPIC L2 SO<sub>2</sub> products produced for appropriate plume altitudes (5 km, 8 km, 13 km)
- SO<sub>2</sub> mass in first EPIC exposure (Nov 28, 18:55 UT; 103.5 kt) equal to flux of 3052 kg/s (~264 kt/d).

# 2022 Mauna Loa eruption (Hawaii)

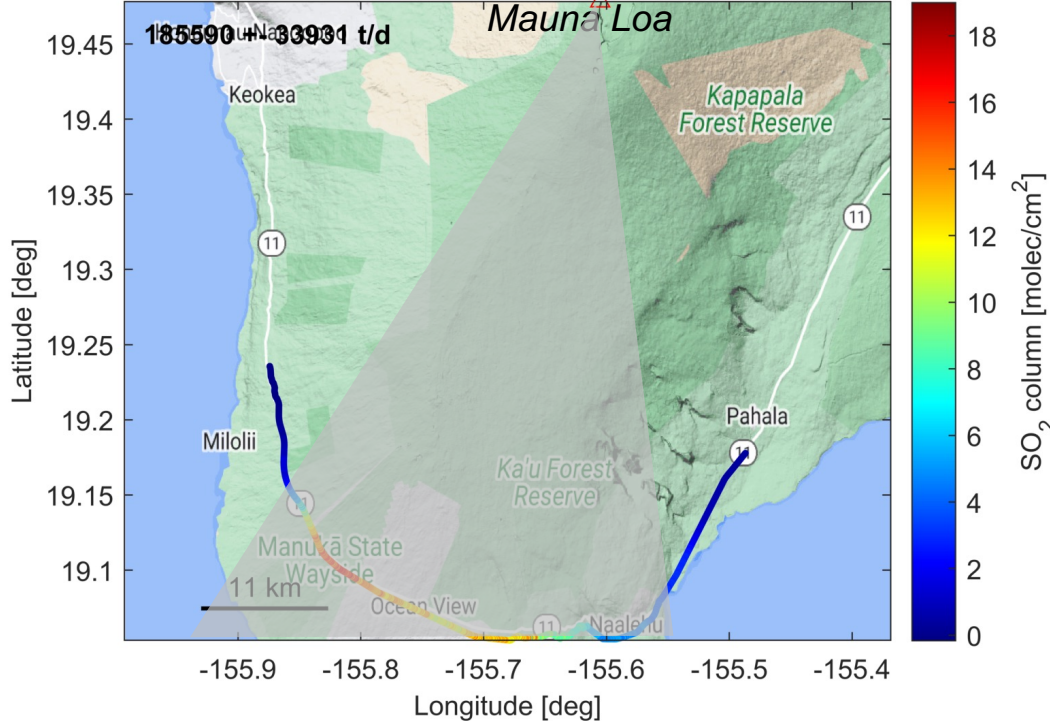

DSCOVER/EPIC - 12/01/2022 18:08 UT

SO<sub>2</sub> mass: 97.69 kt; SO<sub>2</sub> max: 63.81 DU at lon: -154.48, lat: 16.93

Terra/MODIS  
Dec 1, 2023 (20:20 UTC)

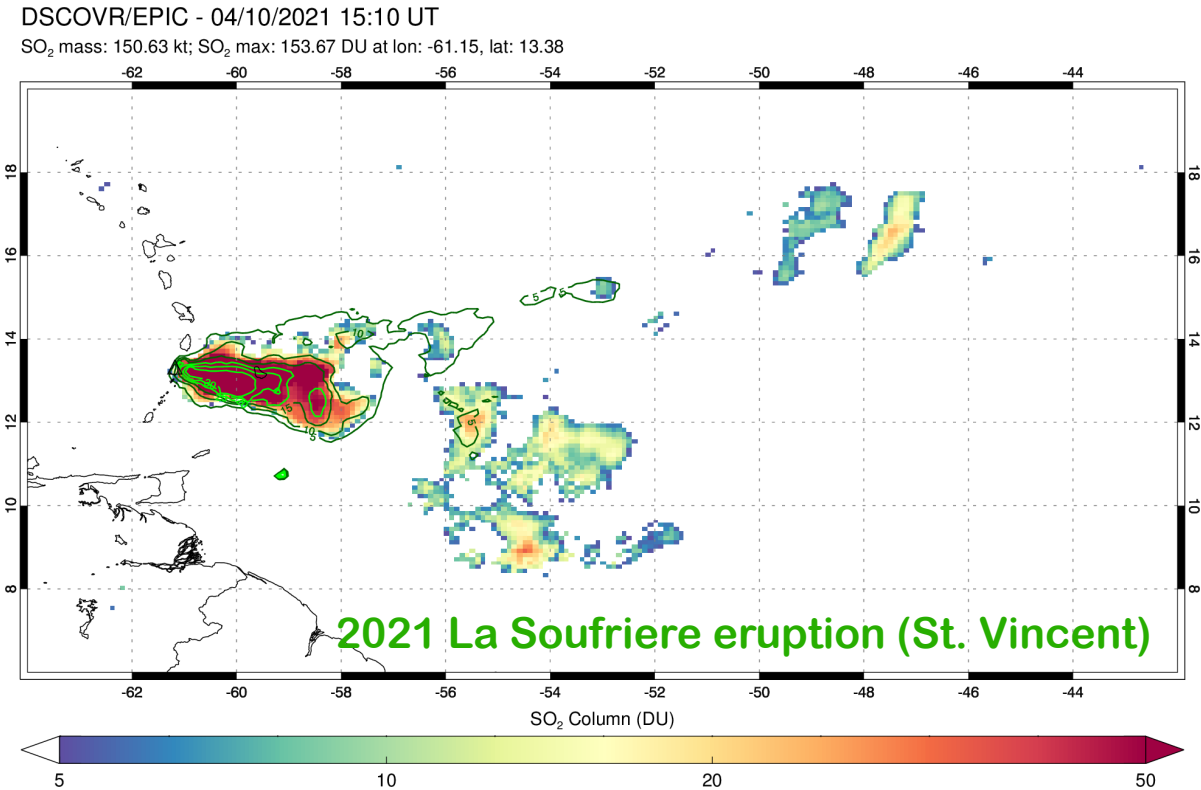

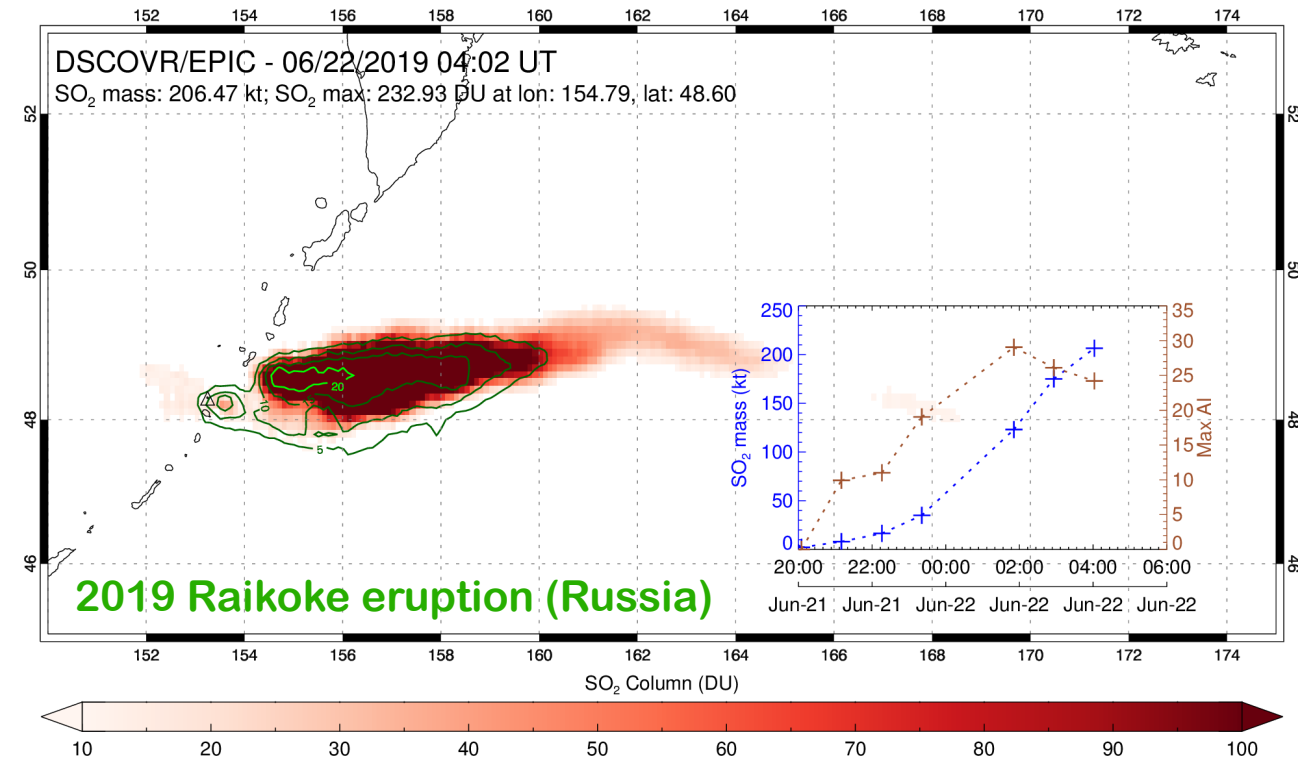

Mauna Loa - 01 Dec 2022, 21:08-21:57 UTC

Ground-based DOAS SO<sub>2</sub> data  
(C. Kern/USGS CVO)

- EPIC detects volcanic plume close to the source due to very high SO<sub>2</sub> column amounts.
- Average ground-based DOAS SO<sub>2</sub> columns in plume: ~300 DU; EPIC maximum: ~100 DU.
- Cloudy conditions (scattering) and plume dilution in EPIC pixel could partly explain differences.

# EPIC volcanic ash and SO<sub>2</sub> retrievals

- Volcanic ash impacts SO<sub>2</sub> measurements in most (all?) explosive volcanic eruption clouds.
- Modeling volcanic ash and cloud optical properties at EPIC UV wavelengths (317, 325, 340, 388 nm).
- Testing/debugging VLIDORT 2.8.5 vs. Arizona RTM (ash particle effective radii of 4 μm and 6 μm).
- Scripts to generate aerosol-cloud LUTs are available from EPIC UV Aerosol team.
- Test using Raikoke eruption (fixed cloud and ash vertical profiles and geometry).

# Summary and future plans

- EPIC volcanic SO<sub>2</sub> science paper in preparation.
- Continue development of EPIC UV ash-SO<sub>2</sub> retrievals in collaboration with EPIC UV Aerosol team.
- Improve low-end EPIC SO<sub>2</sub> sensitivity by applying machine learning techniques to EPIC radiances?
- Improve SO<sub>2</sub> retrieval for higher SZA by expanding the radiance look-up tables.
- If a sufficiently large volcanic eruption occurs, attempt higher-cadence EPIC imaging (~20-30 minute repeat).
- Comparisons between EPIC and geostationary GK2B/GEMS observations of volcanic SO<sub>2</sub> (requires large eruption in Japan, Indonesia or the Philippines, or drifting SO<sub>2</sub> cloud).
